**Name:** Sai Surya Musthyala

**Regd. no:** 2303A52437

## Lab 3: Prompt Engineering – Improving Prompts and Context Management

### Task Description-1

- Progressive Prompting for Calculator Design: Ask the AI to design a simple calculator program by initially providing only the function name. Gradually enhance the prompt by adding comments and usage examples.

The screenshot shows a Jupyter Notebook cell containing Python code for a calculator application. The code defines a function `calculator` that takes three parameters: `num1`, `num2`, and `operation`. It includes docstrings and a dictionary of operations with lambda functions. The code then checks if the operation is in the dictionary and returns the result or an error message. Finally, it demonstrates the usage of the calculator with some example prints.

```
● calculator_app.py
1 def calculator(num1, num2, operation):
2     """
3         A simple calculator that performs operations based on function name.
4         Parameters:
5             num1 (float): First number
6             num2 (float): Second number
7             operation (str): Operation to perform ("add", "subtract", "multiply", "divide", "power", "modulo")
8         Returns:
9             float: Result of the operation
10        """
11
12    operations = {
13        'add': lambda a, b: a + b,
14        'subtract': lambda a, b: a - b,
15        'multiply': lambda a, b: a * b,
16        'divide': lambda a, b: a / b if b != 0 else "Error: Division by zero",
17        'power': lambda a, b: a ** b,
18        'modulo': lambda a, b: a % b if b != 0 else "Error: Modulo by zero"
19    }
20
21    if operation.lower() in operations:
22        result = operations[operation.lower()](num1, num2)
23        return result
24    else:
25        return f"Error: Unknown operation '{operation}'. Available: {', '.join(operations.keys())}"
26
27
28 # Example usage
29 if __name__ == "__main__":
30     print(calculator(10, 5, 'add'))
31     print(calculator(10, 5, 'multiply'))
32     print(calculator(10, 5, 'divide'))
33     print(calculator(10, 5, 'power'))
34     print(calculator(10, 5, 'modulo'))
```

```

# calculator_app.py: ©Calculator
# Test 1: Addition
print("\n[1] ADDITION: calculator(10, 5, 'add')")
result = calculator(10, 5, 'add')
print(f"\tResult: {result}")
print(f"\t\tCalculation: 10 + 5 = {result}")

# Test 2: Subtraction
print("\n[2] SUBTRACTION: calculator(10, 5, 'subtract')")

## Task Description-3

- Few-Shot Prompting for Prime Number Validation: Provide multiple input output examples for a function that checks whether a number is prime. Observe how few-shot prompting improves correctness.

The screenshot shows a code editor with Python code for a prime number checker and an adjacent AI task pane.

**Code (isPrime\_function.py):**

```
● isPrime_function.py > ⓘ isPrime
1 def isPrime(n):
2     """
3         Checks whether a number is prime.
4         A prime number is a natural number greater than 1 that has no positive divisors other than 1 and itself.
5         Args:
6             n: An integer to check
7         Returns:
8             True if n is prime, False otherwise
9         Edge cases handled:
10            - Negative numbers: False
11            - Zero: False
12            - One: False
13            - Two: True (smallest prime)
14        """
15    # Handle edge cases: negative numbers, 0, and 1
16    if n <= 1:
17        return False
18
19    # 2 is the smallest prime number
20    if n == 2:
21        return True
22
23    # Even numbers (except 2) are not prime
24    if n % 2 == 0:
25        return False
26
27    # Check divisibility by odd numbers up to √n
28    # If n has a divisor greater than √n, it must also have a divisor less than √n
29    i = 3
30    while i * i <= n:
31        if n % i == 0:
32            return False
33        i += 2 # Only check odd numbers
34
35    return True
36
37 # Test cases based on provided examples
38
```

**Terminal:**

```
All tests passed: True
```

**AI Task Pane (PRIME NUMBER CHECKING FUNCTION -)**

Task: Implement a function `isPrime()` that checks whether a number is prime.

Below are multiple input-output examples for the AI to infer correct logic and handle edge cases properly.

| Example:  | Input: 5      | Output: false |
|-----------|---------------|---------------|
| Input: 0  | Output: false |               |
| Input: 1  | Output: false |               |
| Input: 2  | Output: true  |               |
| Input: 3  | Output: true  |               |
| Input: 4  | Output: false |               |
| Input: 9  | Output: false |               |
| Input: 11 | Output: true  |               |
| Input: 17 | Output: true  |               |
| Input: 20 | Output: false |               |
| Input: 25 | Output: false |               |
| Input: 29 | Output: true  |               |

Requirements:

- Return false for negative numbers, 0, and 1

**Agent:** Auto

The screenshot shows a code editor with Python code for a prime number checker and an adjacent AI task pane.

**Code (isPrime\_function.py):**

```
● isPrime_function.py > ⓘ isPrime
38 # Test cases based on provided examples
39 test_cases = [
40     (5, False),
41     (0, False),
42     (1, False),

Requirements:

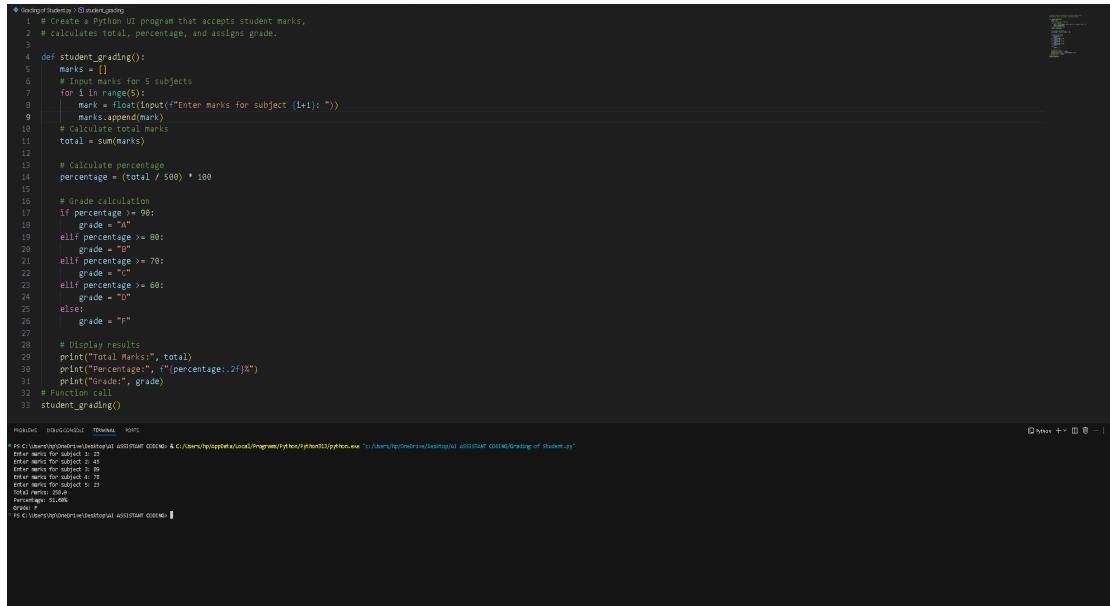

- ✓ All tests passed

**Agent:** Auto

## Task Description-4

- Prompt-Guided UI Design for Student Grading System: Create a user interface for a student grading system that calculates total marks, percentage, and grade based on user input.

## CODE AND OUTPUT:

```
● desktop@Ubuntu:~/Desktop$ python student_grading.py
1 # Create a Python UI program that accepts student marks,
2 # calculate total, percentage, and assigns grade.
3
4 def student_grading():
5     marks = []
6     # Input marks for 5 subjects
7     for i in range(5):
8         mark = float(input("Enter marks for subject {}:".format(i+1)))
9         marks.append(mark)
10    # Calculate total marks
11    total = sum(marks)
12
13    # Calculate percentage
14    percentage = (total / 500) * 100
15
16    # Grade calculation
17    if percentage >= 90:
18        grade = "A"
19    elif percentage >= 80:
20        grade = "B"
21    elif percentage >= 70:
22        grade = "C"
23    elif percentage >= 60:
24        grade = "D"
25    else:
26        grade = "F"
27
28    # Display results
29    print("Total Marks:", total)
30    print("Percentage:", "{:.2f}%".format(percentage))
31    print("Grade:", grade)
32
33 # Function call
student_grading()

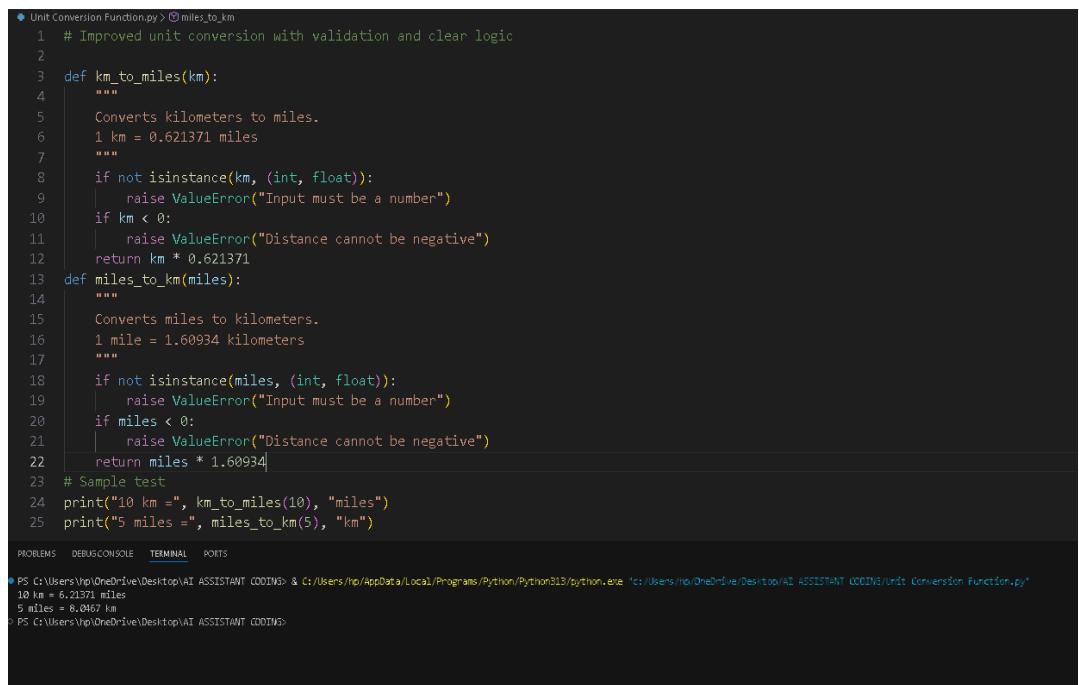

Module: student_grading TOTAL: 100
PS C:\Users\desktop\OneDrive - IIT Kharagpur\assistant\coding\4 C:\Users\desktop\OneDrive - IIT Kharagpur\assistant\coding\grading of student.py
Enter marks for subject 1: 20
Enter marks for subject 2: 40
Enter marks for subject 3: 60
Enter marks for subject 4: 80
Enter marks for subject 5: 20
Total Marks: 200
Percentage: 50.00%
Grade: D

```

## Task Description-5

- Analyzing Prompt Specificity in Unit Conversion Functions: Improving a Unit Conversion Function (Kilometers to Miles and Miles to Kilometers) Using Clear Instructions.

## Expected Output-5

- Analysis of code quality and accuracy differences across multiple prompt variations.

```
● Unit Conversion Function.py > miles_to_km
 1 # Improved unit conversion with validation and clear logic
 2
 3 def km_to_miles(km):
 4     """
 5         Converts kilometers to miles.
 6         1 km = 0.621371 miles
 7     """
 8     if not isinstance(km, (int, float)):
 9         raise ValueError("Input must be a number")
10     if km < 0:
11         raise ValueError("Distance cannot be negative")
12     return km * 0.621371
13 def miles_to_km(miles):
14     """
15         Converts miles to kilometers.
16         1 mile = 1.60934 kilometers
17     """
18     if not isinstance(miles, (int, float)):
19         raise ValueError("Input must be a number")
20     if miles < 0:
21         raise ValueError("Distance cannot be negative")
22     return miles * 1.60934
23 # Sample test
24 print("10 km =", km_to_miles(10), "miles")
25 print("5 miles =", miles_to_km(5), "km")
